## ABSTRACT OF THE DISCLOSURE

A noncontact type signal transmission device performs noncontact transmission of signals between a first member and a second member by using light. The second member moves along a predetermined orbit relative to the first member. A plurality of lightemitting devices are arranged on one of the first and A plurality of light-receiving devices second members. are arranged on the other of the first and second members. Light emitted from the light-emitting devices is received by the light-receiving devices. condensing devices are disposed between the lightemitting devices and the light-receiving devices. Each beam condensing device has a function of condensing light from the light-emitting device in a direction substantially perpendicular to the orbit. The function of each beam condensing device is to increase the amount of light received by each lightreceiving device and to improve light reception sensitivity.
